

LX CLAW

Our new LX CLAW set is designed to support "CrossRamming". Cross-Ramming is a technique used to push deformed body panels back to their original shape. By increasing the surface area, it ensures that any type of material can be pushed away using the rescue cylinder and prevents the cylinder claw from piercing through the material. Claws on both sides ensure perfect grip on all surfaces. The red color scheme is used for better visibility when working in the vehicle. It is applicable for all LUKAS cylinder types, both hose-connected as well as battery-operated. The claw is available in two different sizes and is sold as a set, consisting of a large (L) and a small claw (S). We have paid special attention to the stability of the LX CLAW, fully underbuilt both types have a deformation force of 40 tons.
